

Autograd in NumPy

Luke Zeng

1 Introduction

In this article, we will implement a simple autograd system in NumPy. Autograd is a technique for automatically computing gradients of functions, which is essential for training machine learning models without manually deriving gradients. We will define a class for tensors that can track operations and compute gradients, as well as some basic operations like addition and matrix multiplication. We will also implement a simple ReLU activation function and demonstrate how to use our autograd system to compute gradients for a simple neural network.
